2007 General Facility Information

Prepared by Environmental Programs Directorate

Los Alamos National Laboratory, operated by Los Alamos National Security, LLC, for the U.S. Department of Energy under Contract No. DE-AC52-06NA25396, has prepared this document pursuant to the Compliance Order on Consent, signed March 1, 2005. The Compliance Order on Consent contains requirements for the investigation and cleanup, including corrective action, of contamination at Los Alamos National Laboratory. The U.S. government has rights to use, reproduce, and distribute this document. The public may copy and use this document without charge, provided that this notice and any statement of authorship are reproduced on all copies.

1.0 INTRODUCTION

Pursuant to Section IV.A.2 of the March 1, 2005, Compliance Order on Consent (hereafter, the Consent Order), Los Alamos National Laboratory (LANL or the Laboratory) is providing this annual update to the 2006 General Facility Information (GFI) in a format similar to that of the report submitted in 2006. This annual update includes an explanatory document and a set of plates.

Information on radioactive materials and radionuclides, including the results of sampling and analysis of radioactive constituents, is voluntarily provided to the New Mexico Environment Department (NMED) in accordance with U.S. Department of Energy (DOE) policy.

2.0 SCOPE

Section IV.A.2 of the Consent Order states

The Respondents shall submit to the Department the following information. These submittals are one-time submittals, unless new information becomes available. In that case, the affected submittals shall be updated and resubmitted annually:

1. Facility-wide topographic map;
2. Facility-wide geologic maps, surface geology, and structure contour maps;
3. Maps and tables indicating the surveyed coordinates and locations of all existing springs, wells, and surface water gaging stations;
4. Fault and high-fracture density zone maps;
5. Maps presenting the discharge points of seeps and springs, with tables indicating estimated flow, associated stratigraphic units, and discharge point elevations;
6. Alluvial groundwater maps depicting known saturated aquifer thickness and extent and suspected extent of contamination;
7. Perched-intermediate groundwater maps presenting aquifer thickness and flow direction data, and known and suspected vertical and lateral extents of contamination;
8. Regional groundwater maps depicting measured groundwater elevations and known flow direction(s);
9. The Facility's existing Hydrogeologic Atlas, including water-level contour map of regional aquifer and known radii-of-effects from pumping of municipal supply wells;
10. Diagrams using representative data showing groundwater flow regimes as indicated by water chemistry (e.g., Stiff, Piper diagrams) for all groundwater zones; and
11. Periodic water level data presented graphically and in tabular format.

The information shall be submitted to the Department, in hard copy and CD-ROM, beginning 30 days after the effective date of this Consent Order, and no later than March 31 of each subsequent calendar year.

This annual report includes only those items that have been updated since March 31, 2006. Table 2.0-1 below describes those maps provided as part of this annual update.

3.0 DESCRIPTION OF ITEMS INCLUDED IN THE ANNUAL UPDATE

The following sections describe the submittal for each of the requirements provided in this annual update.

3.1 Requirement 2: Facility-wide Geologic Maps, Surface Geology, and Structure Contour Maps

The 2006 Hydrogeologic Site Atlas has been updated, and a full description of the updates is included in Appendix C of this report. The update contains new information regarding drill hole contact data for newly completed wells, a discussion of the misfit of 2005 geologic framework model to new contact data, and new information regarding the geology at the regional water table.

3.2 Requirement 3: Maps and Tables Indicating the Surveyed Coordinates and Locations of All Existing Springs, Wells, and Surface Water Gaging Stations

Plates 1 and 2—one each for springs and for monitoring and water supply wells—and Appendix A are provided to meet this requirement.

Springs

Plate 1 shows the surveyed locations of springs at the Laboratory. The U.S. Environmental Protection Agency (EPA) defines seepage as “percolation of water through the soil from unlined canals, ditches, laterals, watercourses, or water storage facilities,” and it defines a spring as “groundwater seeping out of the earth where the water table intersects the ground surface” (available at <http://www.epa.gov/OCEPAterms/sterms.html>). The collection of coordinate-location data for seeps and springs at the Laboratory has historically not distinguished between these features and has classified all water-discharge points from the earth or soil as springs. The locations are derived from six feature data sources, one compiled by the U.S. Geological Survey in cooperation with the EPA and five compiled from Laboratory environmental projects.

In 2004, the six feature data sources were merged into a single theme and reviewed by subject-matter experts (including the NMED–DOE Oversight Bureau) for appropriateness of location survey method, validity of horizontal coordinate values, seep/spring classification, periodic migration of the point of discharge, and consistency for site naming and identification. The point locations were overlain with a digital elevation model to obtain the discharge-point elevation and with publicly available geologic maps to obtain the associated stratigraphic unit. A unique feature identification value is provided to link the feature data to database tables containing such information as spring water flow rate, effluent pH, specific conductance, dissolved oxygen, temperature, oxidation-reduction potential, and chemical constituents.

The seeps and springs feature data presented in Appendix A were derived from the following sources:

- AVLIB Springs, Shapefile WQH_avlib_springs_pnt, ArcView Library, Water Quality and Hydrology Group, Environmental Stewardship Division, 1996
- National Hydrography Dataset Program, Medium Resolution, SubBasins 13020101, 13020102, 13020202, and 13020201; U.S. Geological Survey, 08 October 2004

- Springs, MS Excel Spreadsheet, New Mexico Environment Department, Department of Energy Oversight Bureau, Los Alamos, New Mexico, 03 November 2004
- Springs, Shapefile ER_springs_pnt (2002-0593), Information Management, Environmental Restoration Project, Los Alamos National Laboratory, Los Alamos, New Mexico, November 2002
- Updates for Springs Feature Data Set, New Mexico Environment Department, Department of Energy Oversight Bureau; LANL Environmental Remediation and Surveillance Program, ER Document Number ER2005-0495, July 2005
- Water Quality Database, Shapefile WQH_springs_pnt, Water Quality and Hydrology Group, Environmental Stewardship Division, November 2003

Monitoring and Supply Wells

Plate 2 shows the surveyed locations of groundwater monitoring wells and water-supply wells. The data contain locations and unique descriptive feature attributes for monitoring and supply wells at the Laboratory. The data were compiled from various sources, including field survey, global positioning system units, a historical Laboratory document (Purtymun 1995, 045344), and various technical well reports. Appendix A presents the data used to develop this map.

3.3 Requirement 6: Alluvial Groundwater Maps Depicting Known Saturated Aquifer Thickness and Extent and Suspected Extent of Contamination

Plate 3 is provided as an update to Map 05-0160-7 of the 2006 GFI submittal. Several new wells have been installed in the alluvial aquifer in Sandia Canyon since the 2006 GFI submittal. These new alluvial wells are designated SCA-1, SCA-2, SCA-3, SCA-4, and SCA-5 (Kleinfelder 2006, 095121). These wells were drilled to determine the nature and extent of chromium contamination in the alluvial aquifer and to aid in constraining the extent of alluvial saturation.

Filtered analytical data collected between January 1, 2006, and January 1, 2007, were evaluated to update the maps in this report. Those locations where the 2006 data indicated analytes with concentrations above Consent Order screening levels are shown in Plate 3. Appendix B contains the supporting data that can also be found at <http://wqdbworld.lanl.gov/>.

Subject-matter experts used this most recent water-quality data and their knowledge of the alluvial systems at the Laboratory to identify general areas where concentrations of analytes are known or suspected (i.e., expected) to exceed screening levels. The concentrations of analytes in alluvial groundwater are known only at a limited number of locations where alluvial wells exist. This map represents the best current understanding of known or suspected areas of contamination but is not intended to be exact. The Laboratory's understanding of the extent of contamination will continue to change over time as new data become available.

Adjacent but discontinuous areas of known or suspected contamination in a reach were connected to depict where contamination might be expected in persistent alluvial groundwater. Although the analytical chemical data used as a basis for this map are quantitative, extrapolation of contamination between and beyond measurement points is speculative, especially at the lateral extent of contamination in alluvial groundwater. This map is considered semiqualitative and should not be used quantitatively.

3.4 Requirement 7: Perched-Intermediate Groundwater Maps Presenting Aquifer Thickness and Flow Direction Data and Known and Suspected Vertical and Lateral Extents of Contamination

Plate 4 is provided as an update to Map 05-0160-6 of the 2006 GFI submittal. A new well has been installed in Sandia Canyon since the 2006 GFI submittal. Well SCI-1 was completed in the intermediate aquifer at a total depth of casing of 378 ft below ground surface (Kleinfelder 2006, 095121) to aid in determining the aquifer's hydraulic properties and the spatial distribution of chromium contamination.

Filtered analytical data obtained from the Laboratory's most recent water-quality data set and dated from January 1, 2006, to January 1, 2007, were used to update this map. Key validated analytes above Consent Order screening levels are shown on the map as point-source information. Appendix B contains the supporting data, which can also be found at <http://wqdbworld.lanl.gov/>.

The levels of contamination in perched-intermediate groundwater are known where perched-intermediate wells exist; no data are currently available that demonstrate the presence of connections between perched zones.

The data presented for each location on the map should be used to describe groundwater conditions at a single point; information is not available to link the chemistry or the lateral extent of perched groundwater from one location to another. In addition, the direction of perched-intermediate groundwater flow cannot be determined because of multiple measurement points in a common perched zone are not available.

3.5 Requirement 8: Regional Groundwater Maps Depicting Measured Groundwater Elevations and Known Flow Direction(s)

Plate 5 contains tables showing analytes detected at concentrations above screening levels or standards. Chromium is present in regional groundwater monitoring well R-28 and is the only contaminant detected in the regional aquifer at concentrations above groundwater standards.

Plate 6 is taken directly from the updates to the 2006 Hydrogeologic Site Atlas (LANL 2006, 093196). The updates are presented in Appendix C. Water table elevation data shown on the map are representative for monthly average water levels in March 2006. This period has been selected because the observed water levels in March are generally the highest for 2006. The direction of groundwater flow in the regional aquifer is also shown on the map. Explanatory text regarding the generation of this map is included in Appendix C.

3.6 Requirement 9: The Facility's Existing Hydrogeologic Atlas, Including Water-level Contour Map of Regional Aquifer and Known Radii-of-effects from Pumping of Municipal Supply Wells

The regional groundwater table map has been updated and is included as Appendix C. Figure C-2.0-1 in Appendix C shows the regional water table contours based on data from regional wells and springs. Data from Screen 4 of regional groundwater monitoring well R-25 are used to define the water table elevations shown in this map.

Figure C-2.0-2 in Appendix C shows the difference in water table elevations between March 2006 and June 2006. Negative values show that water levels are generally at their highest values in March and are lowest in June.

3.7 Requirement 10: Diagrams Using Representative Data Showing Groundwater Flow Regimes as Indicated by Water Chemistry (e.g., Stiff, Piper Diagrams) for All Groundwater Zones

Filtered analytical data from sampling year 2006 were obtained from the Laboratory's most recent water-quality data set and were used to create Stiff diagrams (using AquaChem version 5.0) to geometrically represent point-source water quality. The Stiff diagrams shown in Plates 7–9 are placed adjacent to each well location. The Stiff plots are displayed using one of three color schemes. Brown, green, and blue diagrams and backgrounds help to distinguish between the alluvial, perched-intermediate, and regional groundwater flow regimes, respectively. All Stiff diagrams shown in the map may also be found in Appendix D-1.

The Stiff diagrams displayed for each location on the map may be used to describe general groundwater hydrochemistry at a single point in space and time. Although the data used to generate the Stiff diagrams are quantitative, the horizontal axis presents the data in equivalents. The hydrochemical data are provided in Appendix D-2 (also available at <http://wqdbworld.lanl.gov/>).

3.8 Requirement 11: Periodic Water-level Data Presented Graphically and in Tabular Format

Plate 10 shows groundwater levels in the alluvial aquifer, and Plate 11 shows water-level data obtained from the perched-intermediate aquifer. Plate 12 shows water-level data obtained from wells completed in the regional aquifer. The time-variant plots shown in these maps were generated using automated transducer records and manual or sampling measurements showing piezometric levels in the alluvial, perched-intermediate, and regional groundwater zones from October 2005 to October 2006. Plots without colored backgrounds indicate locations with multiple zones while plots colored brown, green, and blue correspond to the groundwater zones discussed previously in Section 3.7. All time-variant plots, including individual plots for locations with multiple zones, are provided in Appendix E-1. The data used to generate these graphs are provided in Appendix E-2 and can also be found at <http://wqdbworld.lanl.gov/>.

The plots presented in the map represent point-source data specific to a particular location and time. Further interpretation must be considered to delineate equipotentiometric surfaces within the aquifer. The primary purpose of the map is to illustrate the variability of piezometric head with depth over time throughout the Laboratory.

4.0 REFERENCES

The following list includes all documents cited in this report. Parenthetical information following each reference provides the author(s), publication date, and ER ID number. This information is also included in text citations. ER ID numbers are assigned by the Environmental Programs–Environmental and Remediation Support Services (EP-ERSS) Program Records Processing Facility (RPF) and are used to locate the document at the RPF and, where applicable, in the EP-ERSS Program master reference set.

Copies of the master reference set are maintained at the NMED Hazardous Waste Bureau; the U.S. DOE-Los Alamos Site Office; the U.S. EPA, Region 6; and the EP-ERSS Program. The set was developed to ensure that the administrative authority has all material needed to review this document, and it is updated with every document submitted to the administrative authority. Documents previously submitted to the administrative authority are not included.

2007 Hydrogeologic Site Atlas Updates

C-1.0 NEW DATA FOR THE GEOLOGIC FRAMEWORK MODEL

The 2006 Hydrogeologic Site Atlas (LANL 2006, 093196) is based on geologic data available as of August 2005 and the resultant 2005 3-dimensional geologic framework model of the Pajarito Plateau (Cole et al. 2006, 095079). The geologic framework model consists of 58 2-dimensional elevation grids reflecting the tops and bottoms of 29 geologic units. These surfaces (redundantly) define a 3-dimensional geologic volume model. Data from 22 new characterization, intermediate, and alluvial wells have become available since the current 3-dimensional geologic model was developed. These wells/drill holes are listed in Table C-1.0-1, which provides the depth of the holes, their reference code in the geologic contact database, and the associated well report.

The set of new wells includes characterization wells: the R-series wells, intermediate wells, the LAOI and LADP-series wells, and alluvial (SCA-series) and core hole (SCC-series) wells in Sandia Canyon. The new wells of Sandia Canyon are part of the investigation for chromium contamination in groundwater at Los Alamos National Laboratory (LANL or the Laboratory) (Kleinfelder 2006, 095121). Only seven of these wells penetrated to depths greater than 500 ft. Ten of the wells had depths ranging from 100 to 500 ft, while the five alluvial wells had depths less than 100 ft. The locations of these wells are shown in Figure C-1.0-1. All the wells, except for LADP-5, are sited in canyon bottoms.

The spatial relationships of the new wells to pre-existing wells shown in Figure C-1.0-1 indicate which wells could have the greatest impact on future framework models. The deeper characterization wells: R-10, R-17, R-24 and R-27 are located within significant gaps in the data coverage of earlier models.

C-1.1 New Drill Hole Contact Data

Contacts define the surface between geologic rock units of different types or ages. Fifteen of the new wells provide new positions for contacts of geologic units. Two of the five alluvial wells, SCA-4 and SCA-5, provide inexact constraints for the Otowi (Qbof) contacts; the other alluvial wells provide no contact information. Characterization wells R-6i and R-10a are located adjacent to companion wells R-6 and R-10 and thus do not provide additional surface constraints but may be used as quality measures of existing geologic contact identification.

The reduced set of new drill hole data provides little new information for subunits within the upper part of the Tshirege Member of the Bandelier Tuff and only a single new contact point for each of the lower subunits: Qbt 2, Qbt 1vu, and Qbt 1vc. There are seven new control points for contacts of the Cerro Toledo (Qct) unit. These 15 wells provide control data for the Otowi member of the Bandelier Tuff. Twelve of the holes provide controls for surfaces of the Cerros del Rio basalts. The four characterization wells, R-10, R-17, R-24, and R-27, provide important new constraints for deeper pre-Bandelier units in undersampled regions of earlier models.

Tables C-1.1-1 and C-1.1-2 provide the geologic contact positions identified in the set of new wells, both as depths and as elevations. If a stratigraphic unit is identified within a hole, its top and bottom definition extends to include any flows or facies units that are within the stratigraphic interval. For example, if the stratigraphic unit Tpf and the equivalent-age Tb 4 basalt flows have been identified within a drill hole, the top and bottom elevations and depths for stratigraphic unit Tpf reflect the composite value of the combined geologic units. Note that similar tables in the 3-dimensional model report (Cole et al. 2006, 095079) treated the top and bottom definition of the stratigraphic units slightly differently.

C-1.2 Misfit of 2005 Geologic Framework Model to New Contact Data

A rigorous procedure was employed to ensure that modeled surfaces of the 2005 geologic framework model accurately matched the known drill hole contact constraints. As a result, the average (absolute) misfit of the current modeled surfaces to the applied drill hole constraints is approximately a foot with a 95% confidence interval of about 5 ft. A summary of these misfits is provided in Cole et al. (2006, 095079).

The set of new drill hole information obtained since creation of the 2005 geologic framework model allows the quality of the current (2005) model surfaces to be assessed. Because the framework model is an interlocking set of geologic unit volumes, any future change to a contact surface identified by a statistically significant misfit affects at least two geologic units and possibly several more. Significant changes may also affect the conceptual model, requiring the fitting of surfaces with a different geologic bias or paradigm. Because much effort is required to create a coherent, self-consistent model that incorporates updated surfaces, model updates are generally deferred until regionally (sitewide) significant amounts of new data are available. Copies of the current model may be locally updated by other projects using a copy of the sitewide framework model as a starting point for a restricted-extent model with added local constraints. These added constraints generally become a part of the data support for future framework models. This section evaluates the fit of new drill hole data to the current model, highlighting areas of significant local misfit that may require generation of limited-extent local models utilizing the new data.

Misfits of new drill hole data to the existing framework model are of two types: (1) missing or newly identified contacts within the vertical section at the drill site and (2) misfit of measured to modeled contacts at the drill site. Two new wells, characterization wells R-10 and R-17, document the only misfits of the first type. The new intermediate wells R-3i and LAOI-7 characterize typical misfits of the second type.

C-1.2.1 Model Misfit at Well R-10

Well R-10 is located on land of the San Ildefonso Pueblo, east of the Laboratory and New Mexico State Route 4. This well encountered an 86-ft thickness of the basalt unit Tb 2, which represents a set of Pliocene (9.3–8.4 Ma) basalt flows intercalated with sediments and fanglomerates of the Santa Fe Formation. The unit is present beneath most of the eastern portion of the laboratory. It crops out near the Rio Grande to the south but is absent in characterization well R-16, just northeast of the town of White Rock and does not occur in well O-1 (Otowi #1) or the LA-series wells farther north. It has not been identified within White Rock/Rio Grande Canyon to the north/northeast of White Rock. Figure C-1.2-1 shows the location of R-10 relative to the nearby control wells.

The current framework model assumed that the eastern extent of Tb 2 was approximately 1000 ft west of the line connecting the wells O-1 and R-16, for which the unit was absent. The highest known locations and a possible source for flows of Tb 2 occur as outcrops at elevations of 6400 ft northeast of the well O-1. The lack of Tb 2 material in the deep wells O-1 and LA-4, which should intersect this unit, restrict models of flow to the south and require a wrap-around of the flow to eventually reach the locality of well R-10. Although minimal local changes are required to alter existing surfaces to the new data from R-10, a regional analysis of the paleotectonics, including an evaluation of possibly syndepositional faulting, may provide a better conceptual geologic model for the spatial distribution of Santa Fe and older basalt material within this area.

C-1.2.2 Model Misfit at Well R-17

The well R-17 is located within the center of the Laboratory, close to both the known eastern margins of the older (~3 Ma) Tschicoma dacitic flows (Tt 2) from the west, and the western margins of probably younger (~2.5 Ma) basaltic/dacitic flows of the Cerros del Rio basalt field (Tb 4) to the east. The lobate nature of the Tschicoma flows can be seen in their surface expression west of the laboratory and probably continue to depth, as shown in Figure C-1.2-2. Tb 4 flows probably overlap against pre-existing Tt 2 flows and were modeled to illustrate this overlap in the vicinity of wells PM-5 and R-33. The conceptual model for the low north of well CdV-16-3i, between the two eastward-extending lobes of Tt 2, is based on the absence of Tt 2 in the deep characterization well R-25, which penetrated to depths equivalent to an elevation of 5574 ft. The deepest units encountered in the well were facies of the Puye Formation: a 50-ft zone of boulders, followed by a 5-ft zone of pumice and a 10-ft zone of sand and gravel. Figure C-1.2-2 shows the location of R-17 relative to the nearby control wells and the modeled extent of the Tschicoma dacitic flows and the Cerros del Rio basalt field.

The current framework model predicted that the new well R-17 would encounter Cerros del Rio basalts at an elevation of approximately 6300 ft when in fact it penetrated through a 175-ft thickness of the Tschicoma unit beginning at 6351 ft and re-entered the Puye fanglomerates for the remaining 427 ft of the well. The new well data indicate a shallower southward slope for the northern lobe defined by the model, with the bottom of the lobe occurring at a higher elevation than originally modeled. This lobe is spatially higher than the lobe to the south and may post-date and overlap it to the north. As in the case of the Tb 2 unit in R-10, minimal local changes are required to fit the new set of data constraints. Because deep data in this region of the model are sparse, future wells in this region would likely encounter similar types of errors.

C-1.2.3 Model Misfit at Intermediate Wells R-3i and LAOI-7

Misfits at the remaining new wells reflect vertical errors in the model surfaces. Misfits reflect the measured elevations of contacts in the new data set versus (minus) the predicted model values. These surface morphology errors generally occur at a distance from the applied surface constraints. Surface morphology errors may result from the interpolation method used to create the grid surface and/or from improper guidance provided by the set of conceptual contours. Table C-1.2-1 provides a comparison of contact "picks" predicted by the current (fiscal year [FY] 2005) and previous (FY2002) models and actual contact elevations measured at the new drill hole locations.

The ANUDEM gridding algorithm (available at http://www.ncgia.ucsb.edu/conf/SANTA_FE_CD-ROM/main.html [1996]; and at <http://cres.anu.edu.au/outputs/software.php> [2000]) was used to create a majority of the framework model surfaces. This algorithm was designed to accurately model topographic surfaces using point, contour, and stream data. This product is particularly effective where a contact surface reflects the topography of a paleosurface, such as the basal contact of the Bandelier Tuff that reflects to morphology of the pre-existing topography at 1.6 Ma. The product also works well for very large surfaces with varied spatial complexity through utilization of a multigrid approach to handle the varying scale issue and through implementation of locally adaptive interpolation techniques. For very thin units, either the upper or the lower surface was created through use of isopachs. Discrete isopach values were interpolated to a grid through inverse-distance techniques and then contoured to prevent negative thickness values within the final output grid. These grid thickness values were then added or subtracted from the next lower or higher unit surface grid to create the final surface grid of the unit.

The modeled unit surfaces closely adhere to the constraints imposed by the drill holes used to develop the model, and accurately reflect the control of the conceptual surface contours. Large misfits for the new

drill holes occur within the interpolated areas, away from the drill hole control points, and within regions that reflect the influence of the conceptual surface contours. Thus, any large misfits are not to the result of the interpolation technique used to generate the surface but reflect the conceptual characterization of the surface between the drill hole constraints. Misfits of the current and previous geologic framework surfaces to the new drill hole data are provided in Table C-1.2-1.

The best surface exposures of geologic contacts occur within the canyons. Data support for surfaces within the interior portions of the Pajarito Plateau consist primarily of drill hole constraints. The majority of the 214 wells used for the current framework model are less than 500 ft in depth so geographic (x,y) density of the subsurface control decreases with increased depths. The spacing of “hard” constraints may vary from several thousand feet to several miles or more, depending on the depth of the geologic surface below the topographic surface. The 50-ft resolution for the model grids is a small fraction of the typical drill hole spacing. Surfaces interpolated from the drill hole data alone reflect smoothed profiles between control points with some sort of drainage pattern defined by the surface minimums.

Conceptual contours of unit surfaces are created by a hand contouring process that incorporates both the “hard” constraints such as the drill hole contacts as well as the “soft” constraints. These soft constraints may include

- conceptual models of deposition or erosion of the unit,
- surface contact data of undocumented quality,
- cross-section data which may have a two-dimensional bias,
- outcrops of the unit indicating that the bottom contact of the surface is somewhere below the current topography and the top contact of the surface is above the current topography,
- outcrops of older (stratigraphically deeper) units indicating that the surface should go above the current topography,
- internal contacts of the unit within a drill hole, indicating the presence of the unit but not the exact contact position, and/or
- the morphology of already modeled surfaces of stratigraphically or positionally adjacent units.

The conceptual contours enforce a general pattern of morphology, incorporating the additional “soft” constraints.

The hand-contouring process is somewhat similar to many of the mechanized gridding algorithms although it allows a geologic bias to the contouring. A triangulated irregular network is manually created from the drill hole control points and linear interpolation is performed along the lines (edges) connecting pairs of drill holes, identifying elevation points at linearly interpolated values for hundreds of feet (i.e., at 6100, 6200, etc.). Hand contouring is an iterative process that uses the drill hole points and any identified “soft” constraints in an iterative and adaptive manner to integrate local areas into a regional model. Where “hard” data is sparse and “soft” constraints are lacking, the created contours are spaced in an approximately linear manner between the “hard” data.

The conceptual contours used for the computation of the surface model for the bottom of the Cerros del Rio basalt in the vicinity of new wells R-3i and LAOI-7 are shown in Figure C-1.2-3. Because “soft” data are lacking, the contours are evenly spaced between paired wells R-5 and PM-3 and wells R-5 and O-1. The resultant surface grid, colored by 100-ft intervals, closely matches the elevations at the conceptual contours and constraining drill holes. The change in surface gradient is also quite constant. However, more than 100 ft of misfit to the modeled surface occurs at both new wells, LAOI-7 and R-3i. These two

new data points suggest the existence of a steep, east-west trending slope with a 45% gradient to the south, between wells R-3i and O-1, extending to the west. Clearly, the density of the original data set (hard and soft data) is not sufficient to identify the nonlinear surface behavior identified by the new wells.

An evaluation of the other large misfits between modeled contact surfaces and new drill hole data suggest situations similar to those described for the new wells R-3i and LAOI-7. The Cerro Toledo unit, Qct, consists of depositional material deposited on an erosional surface, as was the case of the Tb 4 flows. The unit exhibits an extremely variable thickness, probably reflecting the range of erosion of the underlying Otowi unit. Significant misfits of the modeled surfaces for Qct occur in wells R-17 and R-27. Other large measured misfits between new drill hole data and modeled framework surfaces can also be attributed to the density of the data support used to build the unit surface models.

C-1.3 Impact of New Data on Future Models

Analysis of the current small set of new drill hole data identifies only minor revisions of the geologic framework model. Additional drill hole data will continue to identify and quantify local uncertainties in the modeled surfaces. Deeper characterization wells, especially any located outside of the convex hull of the set of existing drill holes, could provide important regional data support for many of the deeper units, and provide a more robust conceptual tectonic model for the evolution of the plateau. Figure C-1.3-1 provides a contour map of elevations reflecting the depth of well penetration for wells used in the 2005 geologic framework model.

Figure C-1.3-1 highlights potential changes to the current geologic framework model, predicated by post-model contact data identified in new drill holes. These changes are within the uncertainties of the 2005 geologic framework model and reflect the increased resolution of the expanded subsurface data coverage.

Figure C-1.3-2 shows the elevations of the updated regional water table using a 100-ft contour interval. Well locations are provided for reference. This figure is an update to the contour map of the water table that was created for the 2006 General Facility Information report (LANL 2006, 093570).

The map of the geology at the water table (Figure C-1.3-3) was created by intersecting the units of the 2005 framework geologic model with a grid derived from 100-ft contours of the updated regional water table elevations (Figure C-1.3-2).

C-2.0 CONTOUR MAPS OF THE REGIONAL WATER-TABLE ELEVATION

The regional aquifer beneath the Laboratory is a complex hydrogeological system. The top of the aquifer is predominantly under phreatic (water-table) conditions, but zones of local confinement occur as well. The shape of the regional water table is predominantly controlled by the areas of regional recharge to the west (flanks of Sierra de los Valles) and discharge to the east (the Rio Grande and the White Rock Canyon Springs). The structure of the phreatic flow is also impacted by (1) infiltration zones (predominantly along western faults and canyons), (2) medium heterogeneity and (3) discharge zones (water-supply wells and springs). Information about the elevation of the top of the regional aquifer (regional water-table) is provided by existing data from monitoring wells and some of the springs (discharge elevations). Well data were predominantly used to generate the map; spring data are used only in the vicinity of White Rock Canyon. Water-table elevation data shown in the figure (Figure C-2.0-1) are representative for monthly average water-levels in March 2006; this period was selected because the observed water levels in March are generally the highest for 2006. The data are analyzed to create two alternative water table maps by making different conceptual-model assumptions.

Water-level data from wells R-9, R-12, R-4 and R-24 have been excluded from the analyses. Water levels at R-9 and R-12 are substantially lower than the nearby wells. R-9 and R-12 are located very close to water-supply wells (PM-1, O-1). Lack of any water-level variability at R-9 and R-12 from pumping suggests that the low heads at R-9 and R-12 are not representative of a local cone of depression in the vicinity of water-supply pumping, but rather the low water levels may result from the screen locations of R-9 and R-12, which are much deeper than the regional water-table. The measured pressures suggest a deep zone in poor hydraulic connection with rest of the aquifer perhaps because of local low-permeable hydrogeologic stratum that plays the role of a local aquitard. Based on all the available data, R-4 and R-24 appear to be tapping a confined portion of the regional aquifer that may not be representative of the regional water-table elevation.

Figures C-1.3-2 and C-2.0-1 show two alternative maps of water-table elevation. The maps differ in the interpretation of R-25 data: the first map assumes that water level at Screen 5 (6235 ft) defines the regional water-table elevation; the second map uses data from Screen 4 of R-25 (6360 ft) instead. In the second case (Figure C-2.0-1), groundwater recharge along Cañon de Valle has a dominant influence on the shape of water-table.

Well R-25 intersects a 426.5-ft-thick intermediate saturated zone located about 98 ft above the regional aquifer. The intermediate zone is within the Otowi Member and the Puye Formation. The unsaturated zone between the two saturated zones is in Puye Formation, and the regional aquifer is also in Puye Formation. Puye Formation is fully saturated without a zone of separation at R-26, which is just west of R-25. The separation of the saturated zone at R-25 might be a local feature caused by the medium heterogeneity and spatial distribution of infiltration recharge. The thick intermediate zone encountered at R-25 was not observed in the nearby boreholes R-18 and CdV-16-3(i). Therefore, the intermediate zone is either (1) an isolated (no recharge) and stagnant local feature that is in a poor hydraulic communication with the regional aquifer, or (2) an active conduit of flow (recharge) toward the regional aquifer. Based on the available hydrogeological information, it seems that the second option is more probable.

The water-table contours in Figures C-1.3-2 and C-2.0-1 are also impacted by potential recharge along Water Canyon (CdV-R-37-2), Los Alamos Canyon (R-8) and Pueblo Canyon (TW-1). The size of groundwater mounding at TW-1 is not known with any certainty. It might be substantially smaller than represented on the maps. Figure C-1.3-2 also shows the potential flow directions. The flow structure does not strictly abide the flow-net conformity rules. For example, flowpaths are not perpendicular to the equipotential lines in the central portion of the plateau, perhaps because of the impacts of medium heterogeneity and zones of recharges/discharges.

The lowest water-table elevations in 2006 are observed in June. The differences are small so that water-table maps based on June data will be almost identical to the maps presented in Figures C-1.3-2 and C-2.0-1. To emphasize the dissimilarities, a map representing the differences between average water-levels for March and June has been contoured (Figure C-2.0-2). Water levels from June were subtracted from March water levels; as a result, the negative values on the map define that June levels are lower. Some data are collected at well screens that are relatively long and/or are tapping hydrostratigraphic units located much deeper than the water-table. As a result, the observed water level declines at R-15, R-20, R-21, R-8, and R-6 are assumed to be uncertain and are not exactly representative of changes in the water-table elevations. As mentioned earlier, the R-4 and R-24 screens are located in confined zones, and the data have been excluded. Contour lines approximately represent the water-level differences. The observed differences between March and June water levels are small, and they do not impact the general flow directions in the regional aquifer. The causes for the seasonal effects are primarily variations in the water-supply pumping and possibly, to a lesser extent, regional aquifer recharge.

3.0 REFERENCES

The following list includes all documents cited in this appendix. Parenthetical information following each reference provides the author(s), publication date, and ER ID number. This information is also included in text citations. ER ID numbers are assigned by the Environmental Programs Directorate's Records Processing Facility (RPF) and are used to locate the document at the RPF and, where applicable, in the master reference set.

Copies of the master reference set are maintained at the New Mexico Environment Department (NMED) Hazardous Waste Bureau; the U.S. Department of Energy–Los Alamos Site Office; the U.S. Environmental Protection Agency, Region 6; and the Directorate. The set was developed to ensure that the administrative authority has all material needed to review this document, and it is updated with every document submitted to the administrative authority. Documents previously submitted to the administrative authority are not included.

* n.d. = Not detected in model.

Notes:

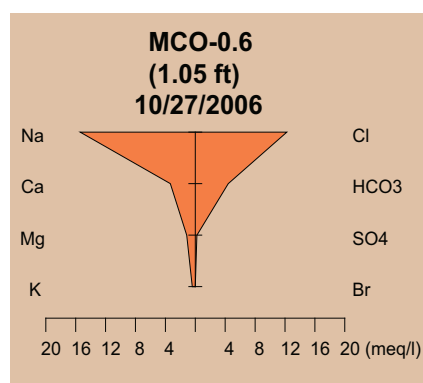

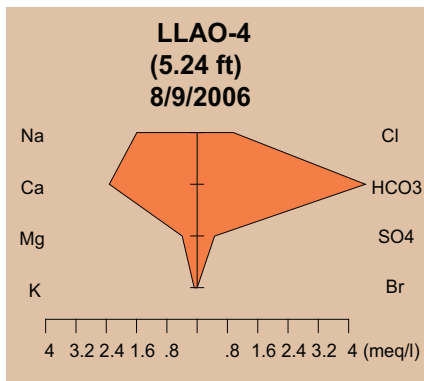

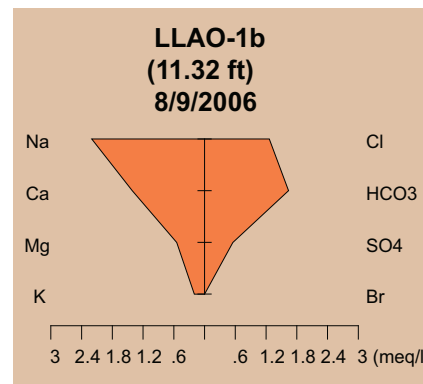

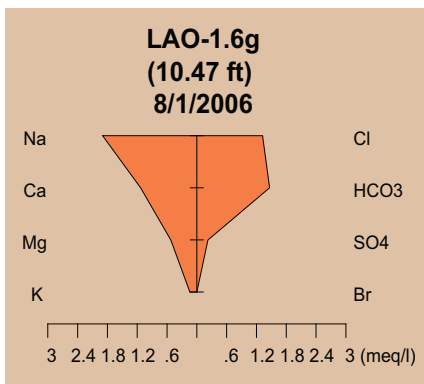

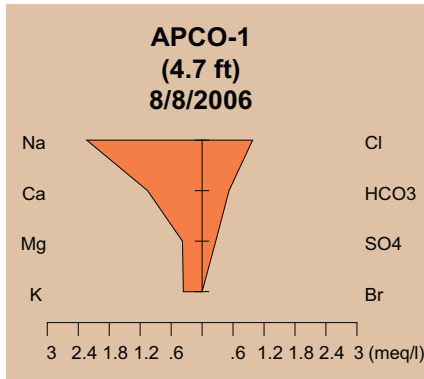

The FY02 model does not include grids for tops of the stratigraphic grids.

Predictions from both the FY02 and the FY05 model are provided. Misfits in blue indicate better fit with the new model; red values indicate a poorer fit.
